**Abstract:** The Rivers in Indonesia often accommodate pollution from all community activities. This happened due to a large number of people who use watersheds for living. One of those rivers is the Karang Mumus River in Samarinda City, East Kalimantan. This study aims to analyze the capacity of the Karang Mumus River pollution load in segments 2, 3 and 4. The analysis model used in this study was the QUAL2Kw and ArcGIS models. The former used to calculate the capacity of river pollution and the latter used to determine land use. The results of the QUAL2Kw Model analysis shown that the capacity of the BOD was exceeded in all segments, COD was exceeded in all segments except segment 3. The entire segment had an allocation of sectoral pollution load originated from domestic activities. This study concluded that the dominant land use of settlements was one of the main causes of this problem.

**Keywords:** capacity load; BOD; COD; TSS; QUAL2Kw model

## ■ INTRODUCTION

Karang Mumus River is located in Samarinda City, East Kalimantan, and is also a subsidiary river of the Mahakam River. The length of the river from upstream to downstream reaches 17 km with a width of 10–15 m. This watershed had densely populated settlements. The majority of the population conducted bathing, washing, and toilet activities directly in this river, causing a lot of garbage thrown into the river and causing pollution. This condition was exacerbated by the existence of economic activities and traditional markets around the riverbanks. This worsened river water quality and affected public health. In addition, this also caused floods and pollution in rivers, household waste had also reduced the quality of water in this river.

Based on the ASPT and WQI, Karang Mumus River recently polluted with *Chironomus sp.* and *Melanoides tuberculata* as codominant taxa [1]. The contamination of PAHs in Karang Mumus River was relatively high because of polluted urban, suburban areas that a lot of commercial

activity and residence [2]. Based on monitoring of water quality in Karang Mumus River in September 2015 held by Environment Agency (BLH) of Samarinda City, pH, BOD, COD, TSS, and Fecal Coliform at some points have exceeded the standard. These various studies were unsettling for the local government, and with various considerations PERDA East Kalimantan Province No. 2 of 2011 concluded that the Management of Water Quality and Water Pollution Control which states that the Karang Mumus River was classified as Class II meaning that the phosphate level in some river points was very high and dangerous.

Some earlier research mentioned several causes influencing the quality of river water, according to Effendy, the speed of river flow and various activities on the banks affected the quality of river water [3]. In line with this, according to Kalavaty, land use in upstream areas made the river water quality polluted [4]. Furthermore, in the rainy season, the flow of the river increased and caused pollution due to the increase in agricultural activities. These were the evidence of how

the use of river water in the upstream areas will affect the water quality in the downstream [5]. There were also social factors such as industrialization, urbanization, and agriculture activities that also affected the river's water physically and chemically for pH, TSS, BOD, COD, nitrate, and phosphorus parameters [6].

One attempt to make sure the level of pollution in the river is by using the Qual2Kw model. QUAL2Kw Model can be used to calculate the capacity of the pollution load according to the desired quality standard. The QUAL2Kw model was also used to determine the future river water quality, so the result of it can be used for the government's policy consideration [7]. The QUAL2Kw model was used to predict water quality in the next few years by calculating the projected population growth and sources of Point Source (PS) and Non Point Source (NPS) pollution [8]. The QUAL2Kw model is useful as a tool for simulating water quality in rivers and measuring the impact of NPS pollution from agriculture [9]. QUAL2Kw can also be used

to simulate DO, BOD, Total Coliform, and Total Nitrogen content in rivers for 10 years [10].

## EXPERIMENTAL SECTION

### Materials

Sampling for water quality checks carried out by purposive sampling. Determination of the sampling time was done by considering the backwater of the Mahakam River using the information that can be accessed at <http://pasanglaut.com>, accessed March 1, 2016, and the conditions of the collection at the river mouth. Based on these considerations, 17 sampling points were determined, namely 10 points in tributaries and drainage, and 7 points were taken in the main river. Sampling was carried out from upstream to downstream without being influenced by the Mahakam River backwater. Location of sampling and division of river segments was presented in Table 1, while the map of sampling points was presented in Fig. 1.

### Instrumentation

Sample from the 17 point location is analyzed in the laboratory for BOD, COD, and TSS parameter. Analysis results were used as the input in the QUAL2Kw Model to determine the load capacity of the pollution of the river in each parameter. The modeling simulated two scenarios, namely, the scenario I in existing conditions and scenario II as a capacity load of pollution based on the standard of the Regulation Province East Kalimantan (No. 2 The Year 2011) about the management of water quality and water pollution control.

### Procedure

There were Steps in the Model QUAL2Kw procedure, they were: first, doing data entry and then running the program. Second, the entry data QUAL2Kw program. The data includes the river segment, distance each segment from upstream to downstream, altitude/river elevation, coordinate segment, Point Source (PS), and Non Point Source (NPS). There were also the climatology and Hydrology data used; the climatology data includes the temperature, wind speed, cloud cover, and the hydrology data includes coefficient manning, wide river,

river discharge, discharge of PS, and NPS [11]. Output results could be viewed in two ways, using the graphs and tables. The output table could be seen on the worksheet WQ Output, while the output graph could be seen on the spatial chart worksheet [12].

The other steps were the calibration and validation of the simulations. The method used was the trial and error model. It included the use of the addition and subtraction of pollution load on the parameters, so the examination of the study will fit the scenario created. The operation of the model was done separately. The pollution load was calculated based on the approach to land use. Land use in the Karang Mumus watershed was dominated by 43.86% settlements and estates 25.42%. Pollution load was calculated by reduction value in scenario II (pollution load capacity) and scenario I (pollution load in the existing condition). The minus result (-) indicates that the pollution load has exceeded capacity and must be reduced. Conversely, if the result is positive (+), it indicates that the capacity still holds the burden of pollution. The output of the program was the magnitude maximum pollution load capable accepted the river [12].

## ■ RESULTS AND DISCUSSION

Pollution load capacity is the maximum amount of pollution loads allowed to be dumped into the water body without causing pollution. Then, the allocation of the burden of pollution is pollution load that can still be accommodated. Analysis of Point Source (PS) and Non Point Source (NPS) pollutants were used to calculate pollution loads. Tributaries and drainage that entered the main river (Sub DAS B2-B11) as PS and were added with NPS calculated from the land use approach. The map of land use and distribution of pollution sources of Karang Mumus watershed were presented in Fig. 2. The land use in Karang Mumus watershed was predominantly residential in the downstream as it is the location of the center of Samarinda City, East Kalimantan Province. Potential pollutant sources in each segment were presented in Table 2.

The settlements have the highest potential of being

a polluting source in Karang Mumus River. It was in accordance with the percentage of land use in Karang Mumus watershed 43.86 of settlement and the city in the downstream area. The water quality of the Karang Mumus River decreased due to pollution. High Fe, Mn, COD, and TSS content in river water were affected by industrial waste, domestic waste, agriculture, and urban area runoff [13]. River water quality with urban land use indicated that water quality was physically polluted and was not suitable for consumption [4]. Fig. 3 presents an overview of the area around Karang Mumus River.

### Pollution Load of BOD, COD, and TSS in Karang Mumus River

The pollution load analysis was done on each segment of the rivers, and it was originated from domestic activity, trash, livestock, agriculture, and building. The analysis of BOD, COD, and TSS are presented in Table 3, 4, and 5.

Percentage	97.67	0.83	1.43	0.07	0.01	100.00

The highest pollution load of BOD, COD, and TSS in all Karang Mumus River segments were originated from domestic activities. We can see from Fig. 2 that

Segment 1 and 2 were dominated by the forestry. On the other hand, segment 3 to segment 5 were dominated by the land use of settlement, including density settlement

on the river banks. The highest pollution load of BOD, COD, and TSS was in segment 5. Urbanization and density of settlements on the river bank were contributed to the water pollution [4].

The high BOD was affected by the source of the contaminant from any famous tourist places [14]. BOD and COD were the indicators of organic pollutants sourced from agriculture and the settlement of domestic waste [15]. In the context of urbanization, many industries across the country also contributed a significant amount of PAHs (Polycyclic Aromatic Hydrocarbon). It was evidenced by the existence of organic pollutants in some rivers across Jakarta City [16].

Yet Geographically, Karang Mumus River has a little elevation in it and there is no any building floodgates that contributes the artificial aeration as the supply of oxygen of which can improve the quality of the water. In fact, the process of self-purification only occurs naturally without any aeration process because turbulence of the flow provides a supply of dissolved oxygen in the water [17].

### Pollution Load Capacity

Calculation of pollution load capacity was done on segment 2, 3, and 4 only. It was because the data taken by the Model should not be influenced by backwater and also marshy areas of the river. After the measurement of discharge was done, it turned out that in segment 1 and 5 the discharge were down on those segments. It happened because the location in segment 1 had a flat topography and the marsh area, while segment 5 was influenced by the backwater of Mahakam River. The pollution load capacity of BOD, COD, and TSS were presented in Table 6, 7, and 8.

Pollution load graphs on the existing conditions (scenario I) and pollution load capacity (scenario II) were presented in Fig. 4, 5, and 6. Zero points on the graph were upstream of Karang Mumus River. The graphs were presented for BOD, COD, and TSS parameters.

Based on Table 6, the pollution load of BOD in the entire segment exceeded the capacity. The highest allocation of the BOD pollution load in segment 4 was

**Table 6.** The pollution load capacity of BOD

Segment	Existing Pollution Load		Pollution Load Capacity		Allocation of Pollution Load	
	mg/L	kg/day	mg/L	kg/day	mg/L	kg/day
2	30.00	885.12	4.60	207.81	-25.40	-677.30

**Fig 4.** Pollution load capacity with the Existing condition of the BOD

**Fig 5.** Pollution load capacity with the existing condition of the COD

**Fig 6.** Pollution load capacity with the existing condition of the TSS

-3,023.29 kg/day, and it should be taken down. It was because the dominant land use in segment 4 was a settlement of 96.43%. This area is the center of Samarinda City with a density of settlement, Mall, Hospital and Traditional Market 'Segiri'. The result of the analysis BOD content in waters using QUAL2Kw concluded that the treatment to improve water quality in the location is needed. It was similar to the statements [8] that the simulation result of BOD by QUAL2Kw was used to determine location to improve water quality.

Based on Table 7, segment 3 still holds the COD pollution load of 398 mg/L with land use of settlement

71.11%. Segment 2 and 4 have COD pollution load exceeding capacity with the allocation of pollution load that must be reduced by 14 mg/L and 80 mg/L. The land use for settlement in segment 2 of 67.22%, and there were small 'tempeh' industries. Segment 4 has the highest COD pollution load is 279.86 mg/L. It was because of the influence of dominant land use settlement of 96.43%. This area is the center of Samarinda City density settlements, Mall, Hospital, and Big Market 'Segiri'. A lot of residential settlements in riverbank with residents' daily activities such as bath, washing, and toilet to the river. It affected COD content because of the many organic compounds degraded in the water.

Based on Table 8, The TSS pollution load across the segment of the river still met the capacity. The pollution load of TSS in segment 4 was approaching capacity. It made sense because there are shopping malls/shopping centers, density residential, hotel, and hospital. TSS compound affected by runoff from the rainwater. The concentration of pollutants in the river is influenced by storm characteristic runoff and land uses [18]. Pollution load capacity for BOD, COD, and TSS was influenced by pollution load coming from the waste of community activities in settlements; it was necessary to be supervised [19].

The map of the capacity of pollution load BOD, COD and TSS presented in Fig. 7 showed the spatial

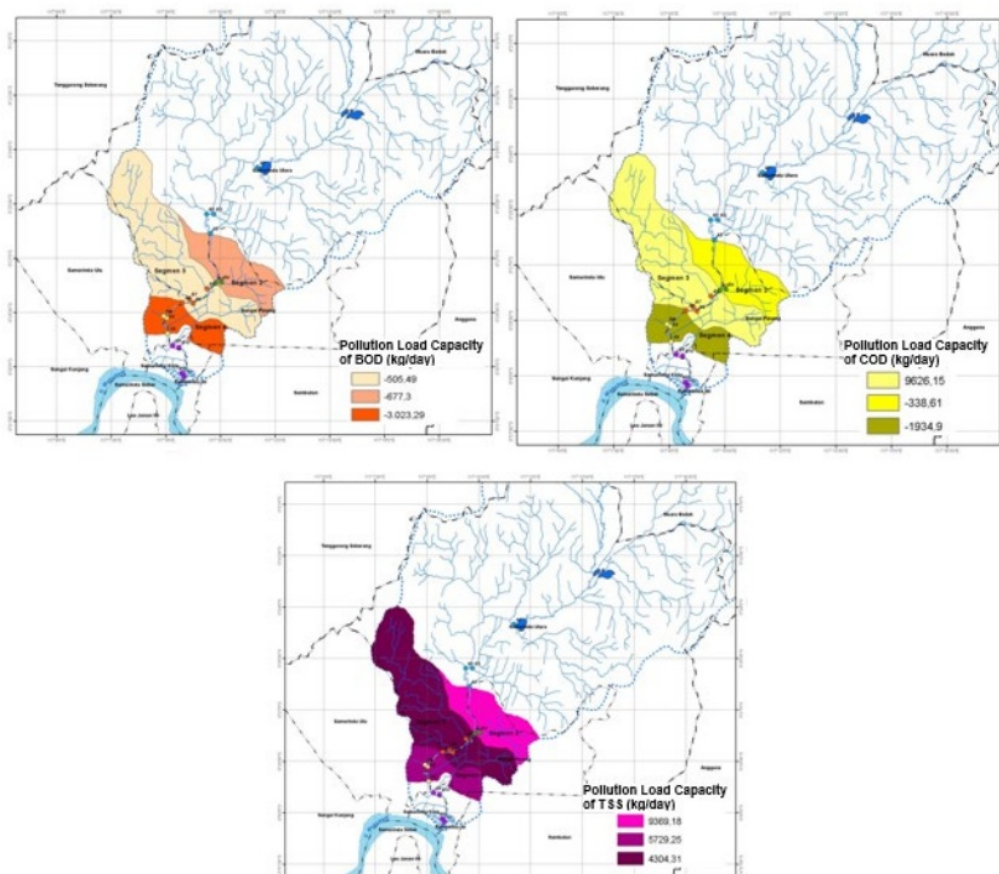

Fig 7. Spatial distribution of pollution load capacity for BOD, COD, and TSS

distribution of the pollution load capacity in the Karang Mumus watershed.

#### Allocation of Pollution Load

Allocation of sector pollution load for BOD, COD, and TSS were presented in Table 9, 10, and 11. It was calculated based on land use percentage in Karang Mumus watershed.

Based on Table 9, the highest allocation sector of pollution load for BOD were originated from the domestic activity from settlements. The highest domestic sector of the BOD pollution load that must be reduced is -2,957.37 kg/day in segment 4, with the dominant land use settlement of 96.43%.

Based on Table 10, the highest allocation sector of pollution load for COD was from the domestic sector. The highest domestic sector of COD pollution load that must be reduced is -1,874.55 kg/day in segment 4, with dominant land use settlement of 96.43%. Segment 3 was still capable of accommodating COD of 8,299.08 kg/day of the domestic sector. Settlements in segment 3 of 71.11% were smaller than segment 4. The allocation sector of pollution load for COD should be reduced in segment 2 is -299.71 kg/day with land use 67.22%. There were small 'tempeh' industries in segment 2, thus causing the pollution load of COD exceeding the capacity, although having the smallest settlement compared to segment 3 and 4.

**Table 9.** Allocation of sector pollution load for BOD

Segment	Allocation of Sector Pollution Load (kg/day)					Total
	Domestic	Trash	Livestock	Agriculture	Building	
2	-615.93	-5.21	-20.74	-35.43	0.00	-677.30
3	-448.74	-3.80	-15.64	-37.32	0.00	-505.49
4	-2,957.37	-25.02	-39.58	-1.31	0.00	-3,023.29
Total	-4,022.04	-34.03	-75.96	-74.06	0.00	-4,206.09

(-) indicates the pollution load must be reduced

**Table 10.** Allocation of sector pollution load for COD

Segment	Allocation of Sector Pollution Load (kg/day)					Total
	Domestic	Trash	Livestock	Agriculture	Building	
2	-299.71	-2.54	-17.55	-18.81	0.00	-338.61
3	8,299.08	70.21	503.96	752.90	0.00	9,626.15
4	-1,874.55	-15.86	-43.59	-0.91	0.00	-1,934.90
Total	6,124.82	51.82	442.82	733.18	0.00	7,352.64

(-) indicates the pollution load must be reduced

**Table 11.** Allocation of sector pollution load for TSS

Segment	Allocation of Sector Pollution Load (kg/day)					Total
	Domestic	Trash	Livestock	Agriculture	Building	
2	9,016.31	76.28	274.12	2.48	-	9,369.18
3	4,137.54	35.00	130.77	0.99	-	4,304.31
4	5,614.02	47.49	67.60	0.13	-	5,729.25
Total	18,767.87	343.18	1,853.82	210.81	-	42,972.41

Based on Table 11, the highest allocation sector of pollution load came from the domestic activity for segment 2, 3 and 4. The whole segment was still capable of holding TSS pollution load, the highest in segment 2 of 9,016.31 kg/day and lowest in segment 3 of 4,137.54 kg/day. It was due to the measurement was conducted at a time when the rain did not occur.

Similar to the statement of Baherem et al. [19], the pollution load capacity of BOD, COD, and TSS sources are originated from the waste of community activities in settlements. It means that public awareness and participation are not adequate to save the river from pollutants. Cooperation between stakeholder and communities are needed to manage bank erosion and agricultural practices aiming to minimize soil erosion in the catchment and sediment input to the river [20].

Based on the spatial distribution of pollution load capacity analysis, we can see more detailed information about the location that needs to be considered by the government as an effort to manage the environment. In addition, the calculation of sector pollution load

allocation provided information about the dominant pollutant source. It can help the government efforts to control water pollution from the source. Hence, the collaboration involving all stakeholder are needed to develop a good river management especially for the communities who lives around the river to always maintain and improve river water quality [21].

## CONCLUSION

The urban areas with the predominantly residential land have potential high pollution load to parameters of BOD, COD, and TSS. Karang Mumus River segment 2, 3 and 4 have a BOD capacity exceeded. Segment 3 was still capable of accommodating COD, and segment 2, 3 and 4 still holds the TSS.

## ACKNOWLEDGMENTS

Loads of Thank for the Environment Government of Samarinda City, River Area Mahakam-Berau Government who gave the secondary data. Thanks to Mr. Agus, Mr. Irwan, Mr. Hardi, Mrs. Yuli and the team

who helped to measurement and collect data in the field. Thanks for Health Laboratory Samarinda Province for helping the measurement of the laboratory test. Finally, thanks a lot for Kemenristek Dikti, which granted the funding to do this research, with the contract number of 124/SP2H/PPM/DRPM/IV/2017.
